Bently Nevada Machinery Condition Monitoring

Description

The 3500/42M Proximitor Seismic Monitor:

- Protects machinery by continuously comparing monitored parameters against configured alarm setpoints to drive alarms.
- Communicates essential machine information to both operations and maintenance personnel.

The 3500/42M Proximitor Seismic Monitor is a four-channel monitor that accepts input from proximity and seismic transducers. It conditions the signal to provide vibration and position measurements and compares the conditioned signals with user-programmable alarms.

You can program each channel using the 3500 Rack Configuration Software to monitor and report:

- | | | |
|--------------------|------------------------------|-------------------|
| - Radial vibration | - REBAM | - Thrust position |
| - Acceleration | - Differential expansion | - Shaft absolute |
| - Eccentricity | - Circular acceptance region | - Velocity |

The monitor channels are programmed in pairs and can perform up to two of the listed functions at a time. For example, Channels 1 and 2 can perform one function while channels 3 and 4 perform another or the same function.

Each channel, depending on configuration, typically conditions its input signal to generate various parameters called **static values**. You can configure **alert setpoints** for each active static value and danger setpoints for any two of the active static values.

REBAM Channels

The following graphs show the maximum machine speed allowed for a monitor channel pair configured for REBAM. The maximum speed depends on the number of rolling elements in the bearing.

The graphs are generated with the following assumptions:

- The rotor lowpass filter corner is set at 3.2 times the shaft speed.
- The spike highpass filter corner is set at four times the element pass frequency for the outer race (BPFO).
